

## thy.1 Defining Functions using Self-Reference

cmp:thy:sf:  
sec

It is generally useful to be able to define functions in terms of themselves. For example, given computable functions  $k$ ,  $l$ , and  $m$ , the fixed-point lemma tells us that there is a partial computable function  $f$  satisfying the following equation for every  $y$ :

$$f(y) \simeq \begin{cases} k(y) & \text{if } l(y) = 0 \\ f(m(y)) & \text{otherwise.} \end{cases}$$

Again, more specifically,  $f$  is obtained by letting

$$g(x, y) \simeq \begin{cases} k(y) & \text{if } l(y) = 0 \\ \varphi_x(m(y)) & \text{otherwise} \end{cases}$$

and then using the fixed-point lemma to find an index  $e$  such that  $\varphi_e(y) = g(e, y)$ .

For a concrete example, the “greatest common divisor” function  $\text{gcd}(u, v)$  can be defined by

$$\text{gcd}(u, v) \simeq \begin{cases} v & \text{if } 0 = 0 \\ \text{gcd}(\text{mod}(v, u), u) & \text{otherwise} \end{cases}$$

where  $\text{mod}(v, u)$  denotes the remainder of dividing  $v$  by  $u$ . An appeal to the fixed-point lemma shows that  $\text{gcd}$  is partial computable. (In fact, this can be put in the format above, letting  $y$  code the pair  $\langle u, v \rangle$ .) A subsequent induction on  $u$  then shows that, in fact,  $\text{gcd}$  is total.

Of course, one can cook up self-referential definitions that are much fancier than the examples just discussed. Most programming languages support definitions of functions in terms of themselves, one way or another. Note that this is a little bit less dramatic than being able to define a function in terms of an *index* for an algorithm computing the functions, which is what, in full generality, the fixed-point theorem lets you do.
