## lam.1 The Syntax of the Lambda Calculus

cmp:lam:syn: sec One starts with a sequence of variables  $x, y, z, \ldots$  and some constant symbols  $a, b, c, \ldots$ . The set of terms is defined inductively, as follows:

- 1. Each variable is a term.
- 2. Each constant is a term.
- 3. If M and N are terms, so is (MN).
- 4. If M is a term and x is a variable, then  $(\lambda x. M)$  is a term.

The system without any constants at all is called the *pure* lambda calculus. We will follow a few notational conventions:

- 1. When parentheses are left out, application takes place from left to right. For example, if M, N, P, and Q are terms, then MNPQ abbreviates (((MN)P)Q).
- 2. Again, when parentheses are left out, lambda abstraction is to be given the widest scope possible. From example,  $\lambda x.\,MNP$  is read  $\lambda x.\,(MNP)$ .
- 3. A lambda can be used to abstract multiple variables. For example,  $\lambda xyz.\,M$  is short for  $\lambda x.\,\lambda y.\,\lambda z.\,M$ .

For example,

 $\lambda xy. xxyx\lambda z. xz$ 

abbreviates

$$\lambda x. \lambda y. ((((xx)y)x)\lambda z. (xz)).$$

You should memorize these conventions. They will drive you crazy at first, but you will get used to them, and after a while they will drive you less crazy than having to deal with a morass of parentheses.

Two terms that differ only in the names of the bound variables are called  $\alpha$ -equivalent; for example,  $\lambda x. x$  and  $\lambda y. y$ . It will be convenient to think of these as being the "same" term; in other words, when we say that M and N are the same, we also mean "up to renamings of the bound variables." Variables that are in the scope of a  $\lambda$  are called "bound", while others are called "free." There are no free variables in the previous example; but in

$$(\lambda z. yz)x$$

y and x are free, and z is bound.
