

## tab.1 Introduction

mod:tab:int: **Tableaux** are certain (downward-branching) trees of **signed formulas**, i.e., pairs  
sec consisting of a truth value sign ( $\mathbb{T}$  or  $\mathbb{F}$ ) and a **sentence**

$$\mathbb{T}\varphi \text{ or } \mathbb{F}\varphi.$$

A **tableau** begins with a number of *assumptions*. Each further **signed formula** is generated by applying one of the inference rules. Some inference rules add one or more **signed formulas** to a tip of the tree; others add two new tips, resulting in two branches. Rules result in **signed formulas** where the **formula** is less complex than that of the **signed formula** to which it was applied. When a branch contains both  $\mathbb{T}\varphi$  and  $\mathbb{F}\varphi$ , we say the branch is *closed*. If every branch in a **tableau** is closed, the entire **tableau** is closed. A closed **tableau** constitutes a **derivation** that shows that the set of **signed formulas** which were used to begin the **tableau** are unsatisfiable. This can be used to define a  $\vdash$  relation:  $\Gamma \vdash \varphi$  iff there is some finite set  $\Gamma_0 = \{\psi_1, \dots, \psi_n\} \subseteq \Gamma$  such that there is a closed **tableau** for the assumptions

$$\{\mathbb{F}\varphi, \mathbb{T}\psi_1, \dots, \mathbb{T}\psi_n\}.$$

For modal logics, we have to both extend the notion of **signed formula** and add rules that cover  $\Box$  and  $\Diamond$ . In addition to a sign ( $\mathbb{T}$  or  $\mathbb{F}$ ), **formulas** in modal **tableaux** also have *prefixes*  $\sigma$ . The prefixes are non-empty sequences of positive integers, i.e.,  $\sigma \in (\mathbb{Z}^+)^* \setminus \{\Lambda\}$ . When we write such prefixes without the surrounding  $\langle \rangle$ , and separate the individual **elements** by  $\cdot$ 's instead of  $,$ 's. If  $\sigma$  is a prefix, then  $\sigma.n$  is  $\sigma \frown \langle n \rangle$ ; e.g., if  $\sigma = 1.2.1$ , then  $\sigma.3$  is  $1.2.1.3$ . So for instance,

$$1.2 \mathbb{T} \Box \varphi \rightarrow \varphi$$

is a *prefixed signed formula* (or just a *prefixed formula* for short).

Intuitively, the prefix names a world in a model that might satisfy the **formulas** on a branch of a **tableau**, and if  $\sigma$  names some world, then  $\sigma.n$  names a world accessible from (the world named by)  $\sigma$ .
