Chapter udf

Stages and Ranks

spine.1  Defining the Stages as the $V_\alpha$s

In ??, we defined well-orderings and the (von Neumann) ordinals. In this chapter, we will use these to characterise the hierarchy of sets itself. To do this, recall that in ??, we defined the idea of successor and limit ordinals. We use these ideas in following definition:

Definition spine.1.

\[
\begin{align*}
V_\emptyset &:= \emptyset \\
V_{\alpha^+} &:= \mathcal{P}(V_\alpha) \quad \text{for any ordinal } \alpha \\
V_\alpha &:= \bigcup_{\gamma<\alpha} V_\gamma \quad \text{when } \alpha \text{ is a limit ordinal}
\end{align*}
\]

This will be a definition by transfinite recursion on the ordinals. In this regard, we should compare this with recursive definitions of functions on the natural numbers.\(^1\) As when dealing with natural numbers, one defines a base case and successor cases; but when dealing with ordinals, we also need to describe the behaviour of limit cases.

This definition of the $V_\alpha$s will be an important milestone. We have informally motivated our hierarchy of sets as forming sets by stages. The $V_\alpha$s are, in effect, just those stages. Importantly, though, this is an internal characterisation of the stages. Rather than suggesting a possible model of the theory, we will have defined the stages within our set theory.

spine.2  The Transfinite Recursion Theorem(s)

The first thing we must do, though, is confirm that Definition spine.1 is a successful definition. More generally, we need to prove that any attempt to

\(^1\)Cf. the definitions of addition, multiplication, and exponentiation in ??.
offer a transfinite by (transfinite) recursion will succeed. That is the aim of this section.

Warning: this is very tricky material. The overarching moral, though, is quite simple: Transfinite Induction plus Replacement guarantee the legitimacy of (several versions of) transfinite recursion.

**Theorem spine.2 (Bounded Recursion).** For any term \( \tau(x) \) and any ordinal \( \alpha \),\(^2\) there is a unique function \( f \) with domain \( \alpha \) such that \( (\forall \beta \in \alpha) f(\beta) = \tau(f|\beta) \)

**Proof.** We will show that, for any \( \delta \leq \alpha \), there is a unique \( g_{\delta} \) with domain \( \delta \) such that \( (\forall \beta \in \delta) g(\beta) = \tau(g|\beta) \).

We first establish uniqueness. Given \( g_{\delta_1} \) and \( g_{\delta_2} \), a transfinite induction on their arguments shows that \( g(\beta) = h(\beta) \) for any \( \beta \in \delta \cap \delta = \min(\delta_1, \delta_2) \). So our functions are unique (if they exist), and agree on all values.

To establish existence, we now use a simple transfinite induction (??) on ordinals \( \delta \leq \alpha \).

Let \( g_{\emptyset} = \emptyset \); this trivially behaves correctly.

Given \( g_{\delta} \), let \( g_{\delta +} = g_{\delta} \cup \{ (\delta, \tau(g_{\delta})) \} \). This behaves correctly as \( g_{\delta +} \in \delta \). Given \( g_{\gamma} \) for all \( \gamma \leq \delta \) with \( \delta \) a limit ordinal, let \( g_{\delta} = \bigcup_{\gamma \in \delta} g_{\gamma} \). This is a function, since our various \( g_{\delta} \)'s agree on all values. And if \( \beta \in \delta \) then \( g_{\delta}(\beta) = g_{\delta +} = \tau(g_{\delta +} | \beta) = \tau(g_{\delta} | \beta) \).

This completes the proof by transfinite induction. Now just let \( f = g_{\alpha} \). \( \Box \)

If we allow ourselves to define a term rather than a function, then we can remove the bound \( \alpha \) from the previous result. (In the statement and proof of this result, when \( \sigma \) is a term, we let \( \sigma|\alpha = \{ (\gamma, \sigma(\gamma)) : \gamma \in \alpha \} \).

**Theorem spine.3 (General Recursion).** For any term \( \tau(x) \) we can explicitly define a term \( \sigma(x) \),\(^3\) such that \( \sigma(\alpha) = \tau(\sigma|\alpha) \) for any ordinal \( \alpha \).

**Proof.** For each \( \alpha \), by **Theorem spine.2** are unique \( \alpha^+ \)-approximations, \( f_{\alpha^+} \), and:

\[
f_{\alpha^+}(\alpha) = \tau(f_{\alpha^+} | \alpha) = \tau(\{ (\gamma, f_{\alpha^+} | \gamma) : \gamma \in \alpha \}).
\]

So define \( \sigma(\alpha) \) as \( f_{\alpha^+}(\alpha) \). Repeating the induction of **Theorem spine.2**, but without the upper bound, this is well-defined. \( \Box \)

Note that these results are schemas. Crucially, we cannot expect \( \sigma \) to define a function, i.e., a certain kind of set, since then \( \text{dom}(\sigma) \) would be the set of all ordinals, contradicting the Burali-Forti Paradox (??).

It still remains to show, though, that **Theorem spine.3** vindicates our definition of the \( V_{\alpha} \)s. This may not be immediately obvious; but it will become apparent with a last, simple, version of transfinite recursion.

\(^2\)The term may have parameters.

\(^3\)Both terms may have parameters.
Theorem spine.4 (Simple Recursion). For any terms $\tau_1(x)$ and $\tau_2(x)$ and any set $A$, we can explicitly define a term $\sigma(x)$ such that:

$$
\begin{align*}
\sigma(\emptyset) &= A \\
\sigma(\alpha^+) &= \tau_1(\sigma(\alpha)) & \text{for any ordinal } \alpha \\
\sigma(\alpha) &= \tau_2(\text{ran}(\sigma|_{\alpha})) & \text{when } \alpha \text{ is a limit ordinal}
\end{align*}
$$

Proof. We start by defining a term, $\xi(x)$, as follows:

$$
\xi(x) = \begin{cases} 
A & \text{if } x \text{ is not a function whose domain is an ordinal;} \\
\tau_1(x(\alpha)) & \text{if } \text{dom}(x) = \alpha^+ \\
\tau_2(\text{ran}(x)) & \text{if } \text{dom}(x) \text{ is a limit ordinal}
\end{cases}
$$

By Theorem spine.3, there is a term $\sigma(x)$ such that $\sigma(x)$ has the required properties, by simple transfinite induction (??).

First, $\sigma(\emptyset) = \xi(\emptyset) = A$.
Next, $\sigma(\alpha^+) = \xi(\sigma|_{\alpha^+}) = \tau_1(\sigma|_{\alpha^+}(\alpha)) = \tau_1(\sigma(\alpha))$.
Finally, if $\alpha$ is a limit ordinal, $\sigma(\alpha) = \xi(\sigma|_{\alpha}) = \tau_2(\text{ran}(\sigma|_{\alpha}))$. \(\square\)

Now, to vindicate Definition spine.1, just take $A = \emptyset$ and $\tau_1(x) = \wp(x)$ and $\tau_2(x) = \bigcup x$. So we have vindicated the definition of the $V_\alpha$s!

### spine.3 Basic Properties of Stages

To bring out the foundational importance of the definition of the $V_\alpha$s, we will start with a few results about them.

Lemma spine.5. For each ordinal $\alpha$:

1. Each $V_\alpha$ is a transitive set.
2. Each $V_\alpha$ is a sublative set,\(^5\) i.e., $\forall A(\exists B(A \subseteq B \in V_\alpha) \rightarrow A \in V_\alpha)$.
3. If $\gamma \in \alpha$, then $V_\gamma \in V_\alpha$ (and hence also $V_\gamma \subseteq V_\alpha$ by (1))

Proof. We prove this by a (simultaneous) transfinite induction. For induction, suppose that (1)–(3) holds for each ordinal $\beta < \alpha$.

The case of $\alpha = \emptyset$ is trivial.

Suppose $\alpha = \beta^+$. To show (3), if $\gamma \in \alpha$ then $V_\gamma \subseteq V_\beta$ by hypothesis, so $V_\gamma \in \wp(V_\beta) = V_\alpha$. To show (2), suppose $A \subseteq B \in V_\alpha$ i.e., $A \subseteq B \subseteq V_\beta$; then $A \subseteq V_\beta$ so $A \in V_\alpha$. To show (1), note that if $x \in A \in V_\alpha$ we have $A \subseteq V_\beta$, so $x \in V_\beta$, so $x \subseteq V_\beta$ as $V_\beta$ is transitive by hypothesis, and so $x \in V_\alpha$.

\(^4\)The terms may have parameters.
\(^5\)There’s no standard terminology for “sublativity”. But this seems good.
Suppose \( \alpha \) is a limit ordinal. To show (3), if \( \gamma \in \alpha \) then \( \gamma \in \gamma^+ \in \alpha \), so that \( V_\gamma \in V_{\gamma^+} \) by assumption, hence \( V_\gamma \in \bigcup_{\beta \in \alpha} V_\beta = V_\alpha \). To show (1) and (2), just observe that a union of transitive (respectively, sublative) sets is transitive (respectively, sublative).

**Lemma spine.6.** For each ordinal \( \alpha \), \( V_\alpha \notin V_\alpha \).

**Proof.** By transfinite induction. Evidently \( V_\emptyset \notin V_\emptyset \).

If \( V_\alpha+ \in V_\alpha+ = \wp(V_\alpha) \), then \( V_\alpha+ \subseteq V_\alpha \); and since \( V_\alpha \in V_\alpha+ \) by Lemma spine.5, we have \( V_\alpha \in V_\alpha \). Conversely: if \( V_\alpha \notin V_\alpha \) then \( V_\alpha+ \notin V_\alpha+ \).

If \( \alpha \) is a limit and \( V_\alpha \in V_\alpha = \bigcup_{\beta \in \alpha} V_\beta \), then \( V_\alpha \in V_\beta \) for some \( \beta \in \alpha \); but then also \( V_\beta \in V_\alpha \) so that \( V_\beta \in V_\beta \) by Lemma spine.5 (twice). Conversely, if \( V_\beta \notin V_\beta \) for all \( \beta \in \alpha \), then \( V_\alpha \notin V_\alpha \).

**Corollary spine.7.** For any ordinals \( \alpha, \beta \): \( \alpha \in \beta \) iff \( V_\alpha \in V_\beta \).

**Proof.** Lemma spine.5 gives one direction. Conversely, suppose \( V_\alpha \subseteq V_\beta \). Then \( \alpha \neq \beta \) by Lemma spine.6; and \( \beta \notin \alpha \), for otherwise we would have \( V_\beta \in V_\alpha \) and hence \( V_\beta \in V_\beta \) by Lemma spine.5 (twice), contradicting Lemma spine.6.

All of this allows us to think of each \( V_\alpha \) as the \( \alpha \)th stage of the hierarchy. Here is why.

Certainly our \( V_\alpha \)s can be thought of as being formed in an iterative process, for our use of ordinals tracks the notion of iteration. Moreover, if one stage is formed before the other, i.e., \( V_\beta \in V_\alpha \), i.e., \( \beta \in \alpha \), then our process of formation is cumulative, since \( V_\beta \subseteq V_\alpha \). Finally, we are indeed forming all possible collections of sets that were available at any earlier stage, since any successor stage \( V_\alpha+ \) is the power-set of its predecessor \( V_\alpha \).

In short: with ZF\(^-\), we are almost done, in articulating our vision of the cumulative-iterative hierarchy of sets. (Though, of course, we still need to justify Replacement.)

**spine.4 Foundation**

We have almost articulated the vision of the iterative-cumulative hierarchy in ZF\(^-\). “Almost”, because there is a wrinkle. Nothing in ZF\(^-\) guarantees that every set is in some \( V_\alpha \), i.e., that every set is formed at some stage.

Now, there is a fairly straightforward (mathematical) sense in which we don’t care whether there are sets outside the hierarchy. (If there are any there, we can simply ignore them.) But we have motivated our concept of set with the thought that every set is formed at some stage (see Stages-are-key in ??.) So we will want to preclude the possibility of sets which fall outside of the hierarchy. Accordingly, we must add a new axiom, which ensures that every set occurs somewhere in the hierarchy.

Since the \( V_\alpha \)s are our stages, we might simply consider adding the following as an axiom:
Regularity. \( \forall A \exists \alpha A \subseteq V_\alpha \)

This is von Neumann’s approach (1925). However, for reasons that will be explained in the next section, we will instead adopt an alternative axiom:

**Axiom (Foundation).** \( (\forall A \neq \emptyset) (\exists B \in A) A \cap B = \emptyset. \)

With some effort, we can show (in \( \text{ZF}^- \)) that Foundation entails Regularity:

**Definition spine.8.** For each set \( A \), let:

\[
\begin{align*}
\text{cl}_0(A) &= A, \\
\text{cl}_{n+1}(A) &= \bigcup \text{cl}_n(A), \\
\text{trcl}(A) &= \bigcup_{n < \omega} \text{cl}_n(A).
\end{align*}
\]

We call \( \text{trcl}(A) \) the *transitive closure* of \( A \). The name is apt:

**Proposition spine.9.** \( A \subseteq \text{trcl}(A) \) and \( \text{trcl}(A) \) is a transitive set.

**Proof.** Evidently \( A = \text{cl}_0(A) \subseteq \text{trcl}(A) \). And if \( x \in b \in \text{trcl}(A) \), then \( b \in \text{cl}_n(A) \) for some \( n \), so \( x \in \text{cl}_{n+1}(A) \subseteq \text{trcl}(A) \).

**Lemma spine.10.** If \( A \) is a transitive set, then there is some \( \alpha \) such that \( A \subseteq V_\alpha \).

**Proof.** Recalling the definition of “lsub(\( X \))” from ??, define:

\[
D = \{ x \in A : \forall \delta (x \notin V_\delta) \}
\]

\[
\alpha = \text{lsub}\{ \delta : (\exists x \in A)(x \subseteq V_\delta \land (\forall \gamma \in \delta) x \notin V_\gamma) \}
\]

Suppose \( D = \emptyset \). So if \( x \in A \), then there is some \( \delta \in \alpha \) such that \( x \subseteq V_\delta \), so \( x \in V_\alpha \) by **Lemma spine.5.** Hence \( A \subseteq V_\alpha \), as required.

So it suffices to show that \( D = \emptyset \). For reductio, suppose otherwise. By Foundation, there is some \( B \in D \) such that \( D \cap B = \emptyset \). If \( x \in B \) then \( x \in A \), since \( A \) is transitive, and since \( x \notin D \), it follows that \( \exists \delta \ x \subseteq V_\delta \). So now let

\[
\beta = \text{lsub}\{ \delta : (\exists x \in b)(x \subseteq V_\delta \land (\forall \gamma < \delta) x \notin V_\gamma) \}.
\]

As before, \( B \subseteq V_\beta \), contradicting the claim that \( B \in D \).

**Theorem spine.11.** Regularity holds.

**Proof.** Fix \( A \); now \( A \subseteq \text{trcl}(A) \) by **Proposition spine.9**, which is transitive. So there is some \( \alpha \) such that \( A \subseteq \text{trcl}(A) \subseteq V_\alpha \) by **Lemma spine.10**.
These results show that $\mathbf{ZF}^-$ proves the conditional $\text{Foundation} \Rightarrow \text{Regularity}$. In Proposition spine.19, we will show that $\mathbf{ZF}^-$ proves $\text{Regularity} \Rightarrow \text{Foundation}$. As such, Foundation and Regularity are equivalent (modulo $\mathbf{ZF}^-$). But this means that, given $\mathbf{ZF}^-$, we can justify Foundation by noting that it is equivalent to Regularity. And we can justify Regularity immediately on the basis of Stages-are-key.

**spine.5  Z and ZF: A Milestone**

With Foundation, we reach another important milestone. We have considered theories $\mathbf{Z}^-$ and $\mathbf{ZF}^-$, which we said were certain theories “minus” a certain something. That certain something is Foundation. So:

**Definition spine.12.** The theory $\mathbf{Z}$ adds Foundation to $\mathbf{Z}^-$. So its axioms are Extensionality, Union, Pairs, Powersets, Infinity, Foundation, and all instances of the Separation scheme.

The theory $\mathbf{ZF}$ adds Foundation to $\mathbf{ZF}^-$. Otherwise put, $\mathbf{ZF}$ adds Replacement to $\mathbf{Z}$.

Still, one question might have occurred to you. If Regularity is equivalent over $\mathbf{ZF}^-$ to Foundation, and Regularity’s justification is clear, why bother to go around the houses, and take Foundation as our basic axiom, rather than Regularity?

Setting aside historical reasons (to do with who formulated what and when), the basic reason is that Foundation can be presented without employing the definition of the $V_\alpha$s. That definition relied upon all of the work of section spine.2: we needed to prove Transfinite Recursion, to show that it was justified. But our proof of Transfinite Recursion employed Replacement. So, whilst Foundation and Regularity are equivalent modulo $\mathbf{ZF}^-$, they are not equivalent modulo $\mathbf{Z}^-$. Indeed, the matter is more drastic than this simple remark suggests. Though it goes well beyond this book’s remit, it turns out that both $\mathbf{Z}^-$ and $\mathbf{Z}$ are too weak to define the $V_\alpha$s. So, if you are working only in $\mathbf{Z}$, then Regularity (as we have formulated it) does not even make sense. This is why our official axiom is Foundation, rather than Regularity.

From now on, we will work in $\mathbf{ZF}$ (unless otherwise stated), without any further comment.

**spine.6  Rank**

Now that we have defined the stages as the $V_\alpha$s, and we know that every set is a subset of some stage, we can define the rank of a set. Intuitively, the rank of $A$ is the first moment at which $A$ is formed. More precisely:
Definition spine.13. For each set $A$, $\text{rank}(A)$ is the least $\alpha$ such that $A \subseteq V_\alpha$.\(^6\)

The well-ordering of ranks allows us to prove some important results:

**Proposition spine.14.** For any ordinal $\alpha$, $V_\alpha = \{ x : \text{rank}(x) \in \alpha \}$.\(^7\)

*Proof.* If $\text{rank}(x) \in \alpha$ then $x \subseteq V_{\text{rank}(x)} \in V_\alpha$, so $x \in V_\alpha$ as $V_\alpha$ is sublative (invoking Lemma spine.5 multiple times). Conversely, by definition of “rank” and Trichotomy on ordinals, if $\text{rank}(x) \not\in \alpha$, then $x \not\in V_\beta$ for any $\beta \in \alpha$; and a simple transfinite induction on ordinals up to $\alpha$ shows that $x \not\in V_\alpha$. \(\square\)

**Proposition spine.15.** If $B \in A$, then $\text{rank}(B) \in \text{rank}(A)$.\(^8\)

*Proof.* $A \subseteq V_{\text{rank}(A)} = \{ x : \text{rank}(x) \in \text{rank}(A) \}$ by Proposition spine.14. \(\square\)

Using this fact, we can establish a result which allows us to prove things about all sets by a form of induction:

**Theorem spine.16 (\in-Induction Scheme).** For any formula $\phi$:\(^7\)

$$\forall A((\forall x \in A)\phi(x) \rightarrow \phi(A)) \rightarrow \forall A \phi(A).$$

*Proof.* We will prove the contrapositive. So, suppose $\neg \forall A \phi(A)$. Since every set has a rank, Transfinite Induction (??) tells us that there is a non-$\phi$ of least possible rank. That is: there is some $A$ such that $\neg \phi(A)$ and $\forall x (\text{rank}(x) \in \text{rank}(A) \rightarrow \phi(x))$. Now if $x \in A$ then $\text{rank}(x) \in \text{rank}(A)$, by Proposition spine.15. So $(\forall x \in A)\phi(x) \land \neg \phi(A)$, falsifying the antecedent. \(\square\)

Here is an informal way to gloss this powerful result. Say that $\phi$ is *hereditary* iff whenever every elements of a set is $\phi$, the set itself is $\phi$. Then $\in$-Induction tells you the following: if $\phi$ is hereditary, every set is $\phi$.

To wrap up the discussion of ranks (for now), we’ll prove a few claims which we have foreshadowed a few times.

**Proposition spine.17.** $\text{rank}(A) = \text{lub}_{x \in A} \text{rank}(x)$.\(^9\)

*Proof.* Let $\alpha = \text{lub}_{x \in A} \text{rank}(x)$. By Proposition spine.15, $\alpha \leq \text{rank}(A)$. But if $x \in A$ then $\text{rank}(x) \in \alpha$, so that $x \in V_\alpha$, and hence $A \subseteq V_\alpha$, i.e., $\text{rank}(A) \leq \alpha$. Hence $\text{rank}(A) = \alpha$. \(\square\)

**Corollary spine.18.** For any ordinal $\alpha$, $\text{rank}(\alpha) = \alpha$.\(^9\)

*Proof.* Suppose for transfinite induction that $\text{rank}(\beta) = \beta$ for all $\beta \in \alpha$. Now $\text{rank}(\alpha) = \text{lub}_{\beta \in \alpha} \text{rank}(\beta) = \text{lub}_{\beta \in \alpha} \beta = \alpha$ by Proposition spine.17. \(\square\)

\(^6\)Some books define $\text{rank}(A)$ as the least $\alpha$ such that $A \in V_\alpha$. Since $A \subseteq V_\alpha \iff A \in V_{\alpha+1}$, this is essentially just a notational difference.

\(^7\)Which may have parameters

\(^9\)Spine rev: 666b46f (2020-02-13) by OLP / CC–BY
Finally, here is a quick proof of the result promised at the end of section spine.4, that $\text{ZF}^-$ proves the conditional $\text{Regularity} \Rightarrow \text{Foundation}$. (Note that the notion of “rank” and Proposition spine.15 are available for use in this proof since—as mentioned at the start of this section—they can be presented using $\text{ZF}^- + \text{Regularity}$.)

**Proposition spine.19 (working in $\text{ZF}^- + \text{Regularity}$).** $\text{Foundation}$ holds.

*Proof.* Fix $A \neq \emptyset$, and some $B \in A$ of least possible rank. If $c \in B$ then $\text{rank}(c) \in \text{rank}(B)$ by Proposition spine.15, so that $c \notin A$ by choice of $B$. \(\square\)
