

## story.1 Extensionality

[sth:story:extensionality:](#)  
[sec](#)

The very first thing to say is that sets are individuated by their members. More precisely:

**Axiom** (Extensionality). For any sets  $A$  and  $B$ :  $\forall x(x \in A \leftrightarrow x \in B) \rightarrow A = B$

We assumed this throughout ???. But it bears repeating. The Axiom of Extensionality expresses the basic idea that a set is determined by its elements. (So sets might be contrasted with *concepts*, where precisely the same objects might fall under many different concepts.)

Why embrace this principle? Well, it is plausible to say that any denial of Extensionality is a decision to abandon anything which might even be called *set theory*. Set theory is no more nor less than the theory of extensional collections.

The real challenge in ???, though, is to lay down principles which tell us *which sets exist*. And it turns out that the only truly “obvious” answer to this question is provably wrong.
