

byd.1 Many-Sorted Logic

sec

In first-order logic, variables and quantifiers range over a single **domain**. But it is often useful to have multiple (disjoint) **domains**: for example, you might want to have a **domain** of numbers, a **domain** of geometric objects, a **domain** of functions from numbers to numbers, a **domain** of abelian groups, and so on.

Many-sorted logic provides this kind of framework. One starts with a list of “sorts”—the “sort” of an object indicates the “**domain**” it is supposed to inhabit. One then has **variables** and quantifiers for each sort, and (usually) an **identity predicate** for each sort. Functions and relations are also “typed” by the sorts of objects they can take as arguments. Otherwise, one keeps the usual rules of first-order logic, with versions of the quantifier-rules repeated for each sort.

For example, to study international relations we might choose a language with two sorts of objects, French citizens and German citizens. We might have a unary relation, “drinks wine,” for objects of the first sort; another unary relation, “eats wurst,” for objects of the second sort; and a binary relation, “forms a multinational married couple,” which takes two arguments, where the first argument is of the first sort and the second argument is of the second sort. If we use variables a, b, c to range over French citizens and x, y, z to range over German citizens, then

$$\forall a \forall x [(MarriedTo(a, x) \rightarrow (DrinksWine(a) \vee \neg EatsWurst(x)))]$$

asserts that if any French person is married to a German, either the French person drinks wine or the German doesn’t eat wurst.

Many-sorted logic can be embedded in first-order logic in a natural way, by lumping all the objects of the many-sorted **domains** together into one first-order **domain**, using unary **predicate symbols** to keep track of the sorts, and relativizing quantifiers. For example, the first-order language corresponding to the example above would have unary **predicate symbols** “*German*” and “*French*,” in addition to the other relations described, with the sort requirements erased. A sorted quantifier $\forall x \varphi$, where x is a **variable** of the German sort, translates to

$$\forall x (German(x) \rightarrow \varphi).$$

We need to add axioms that insure that the sorts are separate—e.g., $\forall x \neg(German(x) \wedge French(x))$ —as well as axioms that guarantee that “drinks wine” only holds of objects satisfying the predicate $French(x)$, etc. With these conventions and axioms, it is not difficult to show that many-sorted **sentences** translate to first-order **sentences**, and many-sorted **derivations** translate to first-order **derivations**. Also, many-sorted **structures** “translate” to corresponding first-order **structures** and vice-versa, so we also have a completeness theorem for many-sorted logic.
