The basic notion that relates expressions such as terms and formulas, on the one hand, and structures on the other, are those of value of a term and satisfaction of a formula. Informally, the value of a term is an element of a structure—if the term is just a constant, its value is the object assigned to the constant by the structure, and if it is built up using function symbols, the value is computed from the values of constants and the functions assigned to the functions in the term. A formula is satisfied in a structure if the interpretation given to the predicates makes the formula true in the domain of the structure. This notion of satisfaction is specified inductively: the specification of the structure directly states when atomic formulas are satisfied, and we define when a complex formula is satisfied depending on the main connective or quantifier and whether or not the immediate subformulas are satisfied.

The case of the quantifiers here is a bit tricky, as the immediate subformula of a quantified formula has a free variable, and structures don’t specify the values of variables. In order to deal with this difficulty, we also introduce variable assignments and define satisfaction not with respect to a structure alone, but with respect to a structure plus a variable assignment.

**Definition syn.1 (Variable Assignment).** A variable assignment $s$ for a structure $\mathcal{M}$ is a function which maps each variable to an element of $|\mathcal{M}|$, i.e., $s: \text{Var} \rightarrow |\mathcal{M}|$.

A structure assigns a value to each constant symbol, and a variable assignment to each variable. But we want to use terms built up from them to also name elements of the domain. For this we define the value of terms inductively. For constant symbols and variables the value is just as the structure or the variable assignment specifies it; for more complex terms it is computed recursively using the functions the structure assigns to the function symbols.

**Definition syn.2 (Value of Terms).** If $t$ is a term of the language $\mathcal{L}$, $\mathcal{M}$ is a structure for $\mathcal{L}$, and $s$ is a variable assignment for $\mathcal{M}$, the value $\text{Val}^\mathcal{M}_s(t)$ is defined as follows:

1. $t \equiv c$: $\text{Val}^\mathcal{M}_s(t) = c^\mathcal{M}$.
2. $t \equiv x$: $\text{Val}^\mathcal{M}_s(t) = s(x)$.
3. $t \equiv f(t_1, \ldots, t_n)$:
   $$\text{Val}^\mathcal{M}_s(t) = f^\mathcal{M}(\text{Val}^\mathcal{M}_s(t_1), \ldots, \text{Val}^\mathcal{M}_s(t_n)).$$

**Definition syn.3 (x-Variant).** If $s$ is a variable assignment for a structure $\mathcal{M}$, then any variable assignment $s'$ for $\mathcal{M}$ which differs from $s$ at most in what it assigns to $x$ is called an $x$-variant of $s$. If $s'$ is an $x$-variant of $s$ we write $s' \sim_x s$. 

satisfaction rev: ad37848 (2024-05-01) by OLP / CC–BY
Note that an \( x \)-variant of an assignment \( s \) does not have to assign something different to \( x \). In fact, every assignment counts as an \( x \)-variant of itself.

**Definition syn.4.** If \( s \) is a variable assignment for a structure \( \mathcal{M} \) and \( m \in |\mathcal{M}| \), then the assignment \( s[m/x] \) is the variable assignment defined by

\[
s[m/x](y) = \begin{cases} 
m & \text{if } y \equiv x \\
s(y) & \text{otherwise.}
\end{cases}
\]

In other words, \( s[m/x] \) is the particular \( x \)-variant of \( s \) which assigns the domain element \( m \) to \( x \), and assigns the same things to variables other than \( x \) that \( s \) does.

**Definition syn.5 (Satisfaction).** Satisfaction of a formula \( \varphi \) in a structure \( \mathcal{M} \) relative to a variable assignment \( s \), in symbols: \( \mathcal{M}, s \models \varphi \), is defined recursively as follows. (We write \( \mathcal{M}, s \not\models \varphi \) to mean “not \( \mathcal{M}, s \models \varphi \).”)

1. \( \varphi \equiv \bot \): \( \mathcal{M}, s \not\models \varphi \).
2. \( \varphi \equiv \top \): \( \mathcal{M}, s \models \varphi \).
3. \( \varphi \equiv \varphi(t_1, \ldots, t_n) \): \( \mathcal{M}, s \models \varphi \) iff \( (\text{Val}_s^\mathcal{M}(t_1), \ldots, \text{Val}_s^\mathcal{M}(t_n)) \in R^\mathcal{M} \).
4. \( \varphi \equiv t_1 = t_2 \): \( \mathcal{M}, s \models \varphi \) iff \( \text{Val}_s^\mathcal{M}(t_1) = \text{Val}_s^\mathcal{M}(t_2) \).
5. \( \varphi \equiv \neg \psi \): \( \mathcal{M}, s \models \varphi \) iff \( \mathcal{M}, s \not\models \psi \).
6. \( \varphi \equiv (\psi \land \chi) \): \( \mathcal{M}, s \models \varphi \) iff \( \mathcal{M}, s \models \psi \) and \( \mathcal{M}, s \models \chi \).
7. \( \varphi \equiv (\psi \lor \chi) \): \( \mathcal{M}, s \models \varphi \) iff \( \mathcal{M}, s \models \psi \) or \( \mathcal{M}, s \models \chi \) (or both).
8. \( \varphi \equiv (\psi \rightarrow \chi) \): \( \mathcal{M}, s \models \varphi \) iff \( \mathcal{M}, s \not\models \psi \) or \( \mathcal{M}, s \models \chi \) (or both).
9. \( \varphi \equiv (\psi \leftrightarrow \chi) \): \( \mathcal{M}, s \models \varphi \) iff either both \( \mathcal{M}, s \models \psi \) and \( \mathcal{M}, s \models \chi \), or neither \( \mathcal{M}, s \models \psi \) nor \( \mathcal{M}, s \models \chi \).
10. \( \varphi \equiv \forall x \psi \): \( \mathcal{M}, s \models \varphi \) iff for every element \( m \in |\mathcal{M}| \), \( \mathcal{M}, s[m/x] \models \psi \).
11. \( \varphi \equiv \exists x \psi \): \( \mathcal{M}, s \models \varphi \) iff for at least one element \( m \in |\mathcal{M}| \), \( \mathcal{M}, s[m/x] \models \psi \).

The variable assignments are important in the last two clauses. We cannot define satisfaction of \( \forall x \psi(x) \) by “for all \( m \in |\mathcal{M}| \), \( \mathcal{M}, m \models \psi(m) \).” We cannot define satisfaction of \( \exists x \psi(x) \) by “for at least one \( m \in |\mathcal{M}| \), \( \mathcal{M}, m \models \psi(m) \).” The reason is that if \( m \in |\mathcal{M}| \), it is not a symbol of the language, and so \( \psi(m) \) is not a formula (that is, \( \psi[m/x] \) is undefined). We also cannot assume that we have constant symbols or terms available that name every element of \( \mathcal{M} \), since there is nothing in the definition of structures that requires it. In the standard language, the set of constant symbols is denumerable, so if \( |\mathcal{M}| \) is not enumerable there aren’t even enough constant symbols to name every object.

We solve this problem by introducing variable assignments, which allow us to link variables directly with elements of the domain. Then instead of saying
that, e.g., \( \exists x \psi(x) \) is satisfied in \( \mathfrak{M} \) iff for at least one \( m \in |\mathfrak{M}| \), we say it is satisfied in \( \mathfrak{M} \ relative to \ s \) iff \( \psi(x) \) is satisfied relative to \( s[m/x] \) for at least one \( m \in |\mathfrak{M}| \).

**Example syn.** 6. Let \( \mathcal{L} = \{ a, b, f, R \} \) where \( a \) and \( b \) are constant symbols, \( f \) is a two-place function symbol, and \( R \) is a two-place predicate symbol. Consider the structure \( \mathfrak{M} \) defined by:

1. \( |\mathfrak{M}| = \{ 1, 2, 3, 4 \} \)
2. \( a^\mathfrak{M} = 1 \)
3. \( b^\mathfrak{M} = 2 \)
4. \( f^\mathfrak{M}(x, y) = x + y \) if \( x + y \leq 3 \) and = 3 otherwise.
5. \( R^\mathfrak{M} = \{ \langle 1, 1 \rangle, \langle 1, 2 \rangle, \langle 2, 3 \rangle, \langle 2, 4 \rangle \} \)

The function \( s(x) = 1 \) that assigns 1 \( \in |\mathfrak{M}| \) to every variable is a variable assignment for \( \mathfrak{M} \).

Then
\[
\text{Val}^\mathfrak{M}_s(f(a, b)) = f^\mathfrak{M}(\text{Val}^\mathfrak{M}_s(a), \text{Val}^\mathfrak{M}_s(b)).
\]

Since \( a \) and \( b \) are constant symbols, \( \text{Val}^\mathfrak{M}_s(a) = a^\mathfrak{M} = 1 \) and \( \text{Val}^\mathfrak{M}_s(b) = b^\mathfrak{M} = 2 \).

So
\[
\text{Val}^\mathfrak{M}_s(f(a, b)) = f^\mathfrak{M}(1, 2) = 1 + 2 = 3.
\]

To compute the value of \( f(f(a, b), a) \) we have to consider
\[
\text{Val}^\mathfrak{M}_s(f(f(a, b), a)) = f^\mathfrak{M}(\text{Val}^\mathfrak{M}_s(f(a, b)), \text{Val}^\mathfrak{M}_s(a)) = f^\mathfrak{M}(3, 1) = 3,
\]

since \( 3 + 1 > 3 \). Since \( s(x) = 1 \) and \( \text{Val}^\mathfrak{M}_s(x) = s(x) \), we also have
\[
\text{Val}^\mathfrak{M}_s(f(f(a, b), x)) = f^\mathfrak{M}(\text{Val}^\mathfrak{M}_s(f(a, b)), \text{Val}^\mathfrak{M}_s(x)) = f^\mathfrak{M}(3, 1) = 3,
\]

An atomic formula \( R(t_1, t_2) \) is satisfied if the tuple of values of its arguments, i.e., \( (\text{Val}^\mathfrak{M}_s(t_1), \text{Val}^\mathfrak{M}_s(t_2)) \), is an element of \( R^\mathfrak{M} \). So, e.g., we have \( \mathfrak{M}, s \models R(b, f(a, b)) \) since \( (\text{Val}^\mathfrak{M}_s(b), \text{Val}^\mathfrak{M}_s(f(a, b))) = (2, 3) \in R^\mathfrak{M} \), but \( \mathfrak{M}, s \not\models R(x, f(a, b)) \) since \( (1, 3) \notin R^\mathfrak{M}[s] \).

To determine if a non-atomic formula \( \varphi \) is satisfied, you apply the clauses in the inductive definition that applies to the main connective. For instance, the main connective in \( R(a, a) \to (R(b, x) \lor R(x, b)) \) is the \( \to \), and
\[
\mathfrak{M}, s \models R(a, a) \to (R(b, x) \lor R(x, b)) \text{ iff } \\
\mathfrak{M}, s \not\models R(a, a) \text{ or } \mathfrak{M}, s \models R(b, x) \lor R(x, b)
\]
Since $\mathcal{M}, s \models R(a, a)$ (because $\langle 1, 1 \rangle \in R^{|\mathcal{M}|}$) we can’t yet determine the answer and must first figure out if $\mathcal{M}, s \not\models R(b, x) \lor R(x, b)$:

$$\mathcal{M}, s \models R(b, x) \lor R(x, b) \text{ iff } \mathcal{M}, s \not\models R(b, x) \text{ or } \mathcal{M}, s \models R(x, b)$$

And this is the case, since $\mathcal{M}, s \models R(x, b)$ (because $\langle 1, 2 \rangle \in R^{|\mathcal{M}|}$).

Recall that an $x$-variant of $s$ is a variable assignment that differs from $s$ at most in what it assigns to $x$. For every element of $|\mathcal{M}|$, there is an $x$-variant of $s$:

$$s_1 = s[1/x], \quad s_2 = s[2/x], \quad s_3 = s[3/x], \quad s_4 = s[4/x].$$

So, e.g., $s_2(x) = 2$ and $s_2(y) = s(y) = 1$ for all variables $y$ other than $x$. These are all the $x$-variants of $s$ for the structure $\mathcal{M}$, since $|\mathcal{M}| = \{1, 2, 3, 4\}$. Note, in particular, that $s_1 = s$ ($s$ is always an $x$-variant of itself).

To determine if an existentially quantified formula $\exists x \varphi(x)$ is satisfied, we have to determine if $\mathcal{M}, s[m/x] \models \varphi(x)$ for at least one $m \in |\mathcal{M}|$. So,

$$\mathcal{M}, s \models \exists x (R(b, x) \lor R(x, b)),$$

since $\mathcal{M}, s[1/x] \not\models R(b, x) \lor R(x, b)$ ($s[3/x]$ would also fit the bill). But,

$$\mathcal{M}, s \not\models \exists x (R(b, x) \land R(x, b))$$

since, whichever $m \in |\mathcal{M}|$ we pick, $\mathcal{M}, s[m/x] \not\models R(b, x) \land R(x, b)$.

To determine if a universally quantified formula $\forall x \varphi(x)$ is satisfied, we have to determine if $\mathcal{M}, s[m/x] \models \varphi(x)$ for all $m \in |\mathcal{M}|$. So,

$$\mathcal{M}, s \not\models \forall x (R(x, a) \rightarrow R(a, x)),$$

since $\mathcal{M}, s[m/x] \not\models R(x, a) \rightarrow R(a, x)$ for all $m \in |\mathcal{M}|$. For $m = 1$, we have $\mathcal{M}, s[1/x] \models R(a, x)$ so the consequent is true; for $m = 2, 3, \text{ and } 4$, we have $\mathcal{M}, s[m/x] \not\models R(x, a)$, so the antecedent is false. But,

$$\mathcal{M}, s \not\models \forall x (R(a, x) \rightarrow R(x, a))$$

since $\mathcal{M}, s[2/x] \not\models R(a, x) \rightarrow R(x, a)$ (because $\mathcal{M}, s[2/x] \models R(a, x)$ and $\mathcal{M}, s[2/x] \not\models R(a, x)$).

For a more complicated case, consider

$$\forall x (R(a, x) \rightarrow \exists y R(x, y)).$$

Since $\mathcal{M}, s[3/x] \not\models R(a, x)$ and $\mathcal{M}, s[4/x] \not\models R(a, x)$, the interesting cases where we have to worry about the consequent of the conditional are only $m = 1$.
and $= 2$. Does $M, s[1/x] \models \exists y R(x, y)$ hold? It does if there is at least one $n \in |M|$ so that $M, s[1/x][n/y] \models R(x, y)$. In fact, if we take $n = 1$, we have $s[1/x][n/y] = s[1/y] = s$. Since $s(x) = 1$, $s(y) = 1$, and $\langle 1, 1 \rangle \in R^M$, the answer is yes.

To determine if $M, s[2/x] \models \exists y R(x, y)$, we have to look at the variable assignments $s[2/x][n/y]$. Here, for $n = 1$, this assignment is $s_2 = s[2/x]$, which does not satisfy $R(x, y)$ ($s_2(x) = 2$, $s_2(y) = 1$, and $\langle 2, 1 \rangle \notin R^M$). However, consider $s[2/x][3/y] = s_2[3/y]$. $M, s_2[3/y] \models R(x, y)$ since $\langle 2, 3 \rangle \in R^M$, and so $M, s_2 \models \exists y R(x, y)$.

So, for all $n \in |M|$, either $M, s[m/x] \not\models R(a, x)$ (if $m = 3, 4$) or $M, s[m/x] \models \exists y R(x, y)$ (if $m = 1, 2$), and so

$$M, s \models \forall x (R(a, x) \rightarrow \exists y R(x, y)).$$

On the other hand,

$$M, s \not\models \exists x (R(a, x) \land \forall y R(x, y)).$$

We have $M, s[m/x] \models R(a, x)$ only for $m = 1$ and $m = 2$. But for both of these values of $m$, there is in turn an $n \in |M|$, namely $n = 4$, so that $M, s[m/x][n/y] \not\models R(x, y)$ and so $M, s[m/x] \not\models \forall y R(x, y)$ for $m = 1$ and $m = 2$.

In sum, there is no $m \in |M|$ such that $M, s[m/x] \models R(a, x) \land \forall y R(x, y)$.

**Problem syn.1.** Let $\mathcal{L} = \{c, f, A\}$ with one constant symbol, one one-place function symbol and one two-place predicate symbol, and let the structure $M$ be given by

1. $|M| = \{1, 2, 3\}$
2. $c^M = 3$
3. $f^M(1) = 2$, $f^M(2) = 3$, $f^M(3) = 2$
4. $A^M = \{(1, 2), (2, 3), (3, 3)\}$

(a) Let $s(v) = 1$ for all variables $v$. Find out whether

$$M, s \models \exists x (A(f(z), c) \rightarrow \forall y (A(y, x) \lor A(f(y), x))).$$

Explain why or why not.

(b) Give a different structure and variable assignment in which the formula is not satisfied.
