

## fun.1 Partial Functions

sfr:fun:par: It is sometimes useful to relax the definition of function so that it is not required explanation that the output of the function is defined for all possible inputs. Such mappings are called *partial functions*.  
sec

**Definition fun.1.** A *partial function*  $f: A \rightarrow B$  is a mapping which assigns to every **element** of  $A$  at most one **element** of  $B$ . If  $f$  assigns an element of  $B$  to  $x \in A$ , we say  $f(x)$  is *defined*, and otherwise *undefined*. If  $f(x)$  is defined, we write  $f(x) \downarrow$ , otherwise  $f(x) \uparrow$ . The *domain* of a partial function  $f$  is the subset of  $A$  where it is defined, i.e.,  $\text{dom}(f) = \{x \in A : f(x) \downarrow\}$ .

**Example fun.2.** Every function  $f: A \rightarrow B$  is also a partial function. Partial functions that are defined everywhere on  $A$ —i.e., what we so far have simply called a function—are also called *total functions*.

**Example fun.3.** The partial function  $f: \mathbb{R} \rightarrow \mathbb{R}$  given by  $f(x) = 1/x$  is undefined for  $x = 0$ , and defined everywhere else.

**Problem fun.1.** Given  $f: A \rightarrow B$ , define the partial function  $g: B \rightarrow A$  by: for any  $y \in B$ , if there is a unique  $x \in A$  such that  $f(x) = y$ , then  $g(y) = x$ ; otherwise  $g(y) \uparrow$ . Show that if  $f$  is injective, then  $g(f(x)) = x$  for all  $x \in \text{dom}(f)$ , and  $f(g(y)) = y$  for all  $y \in \text{ran}(f)$ .

**Definition fun.4 (Graph of a partial function).** Let  $f: A \rightarrow B$  be a partial function. The *graph* of  $f$  is the relation  $R_f \subseteq A \times B$  defined by

$$R_f = \{\langle x, y \rangle : f(x) = y\}.$$

**Proposition fun.5.** Suppose  $R \subseteq A \times B$  has the property that whenever  $Rxy$  and  $Rxy'$  then  $y = y'$ . Then  $R$  is the graph of the partial function  $f: X \rightarrow Y$  defined by: if there is a  $y$  such that  $Rxy$ , then  $f(x) = y$ , otherwise  $f(x) \uparrow$ . If  $R$  is also serial, i.e., for each  $x \in X$  there is a  $y \in Y$  such that  $Rxy$ , then  $f$  is total.

*Proof.* Suppose there is a  $y$  such that  $Rxy$ . If there were another  $y' \neq y$  such that  $Rxy'$ , the condition on  $R$  would be violated. Hence, if there is a  $y$  such that  $Rxy$ , that  $y$  is unique, and so  $f$  is well-defined. Obviously,  $R_f = R$  and  $f$  is total if  $R$  is serial.  $\square$
